5 Major changes from order

5.1 Network

5.1.1 Subnet sizes

Originally the subnets were set with /27 netmasks.

We felt this was unneccacarily complicated as it makes it much harder to troubleshoot.

To make troubleshooting easier we made /24 networks, one for each department/relevant section.

5.1.2 Ip-ranges

We also set some rules for what different ip addresses *should* mean.

```
192.168.x.1 - 192.168.x.49: network units 192.168.x.50 - 192.168.x.99: servers 192.168.x.100 - 192.168.x.254: clients
```

This setup makes it easy to identify device based on the ip address when inspecting logs during troubleshooting

The only downside with this is that every address from 1-99 has to be set manually, and the dhcp sets the clients ipadresses.

If you want to know which department a request came from, or is going to, x in the example will tell you what to look up in the documentation.

In hindsight, having 49 addresses for network units is quite overkill on the cloud, with what is supposed to run on it as it looks today. The thought to have that many emerged from the real-world setup scenario, where the company wanted ip-cameras, which then would be put in the 1-49 range.

This could have also been done by having a dedicated subnet for the ipcameras, but it feels nice to keep general rules to make it quick and easy to get an idea of what's happening reading logs.

5.2 Instances

5.2.1 VmServer(2)

Since we are running on the cloud, and after some discussion with our consult hxp, we decided it was unneceedary to have two vm-servers.

The server in question was supposed to be used as a backup incase the main vm-server goes down. But since it's only supposed to host 'in-house' applications, the risk of getting overloaded is small enough that the cost is too great compared to what we would gain.

If the server goes down, it will be easy to get it up and running again, and since we are using volumes, the data is persistant. We would get some downtime, but no data loss.

5.2.2 AnsibleMaster

We decided to use ansible to configure all the machines. To make the process as easy as possible, we wanted to have the ansible master running inside of the cloud. This also means that we don't need to open the ssh-ports to wan on every instance.

6 Terraform

6.1 Prerequisites

This script assumes you already have a router with a specific ID in openstack

Change the ID in terraform/variables.tf to match yours.

It also assumes that you have a ssh key-pair on openstack named Nietzsche,

aswell as the private key named id_rsa in ansible/.ssh/id_rsa You will also need to replace the set ip in the security group allowing ssh from WAN.

In order to give your credentials to openstack

you will need to source the project-script from openstack before running terraform commands.

6.2 Usage

6.2.1 First time

terraform init

6.2.2 Build

terraform apply -auto-approve

For some reason, terraform needs to run the apply command twice to actually set the security groups.

This will make the file-transfer a bit weird.

Terraform is going to time-out on trying to ssh into the machine "AnsibleMaster",

you can cancel this with ^c and re-run the the apply command.

This will set the security groups, and make it possible to transfer the files over ssh.

6.2.3 Destroy

terraform destroy

6.3 Future features

6.3.1 Volumes

We want to link volumes to some machines, to be able to have persistant data, and logs. The idea is to take snapshots of the important data and our logs, and have those snapshots on rolling backups.

6.3.2 VPN

We want to set up a VPN server/service so that a 'client' can work inside the cloud as if you were connected in an office.

7 Planned features

7.1 Prometheus + Grafana

We wanted to implement Prometheus and Grafana services but due to the lack of time we couldn't make it. We worked on it a bit but got worried about implementing into the cloud environment. One group member set it up and got it working on their computer, but didn't know how to set it up securely OpenStack.

7.2 Backups

7.2.1 OpenStack volumes

We wanted to set up some kind of a backup system for the server environment. We wanted to implement the 3-2-1 module. We looked into creating snapshots of volumes however we needed to shutdown the servers to not accidently get bad data.

7.3 VPN

We never got the VPN to work, we figured to improve the networks security it would be beneficial to implement a kind of VPN to encrypt traffic.

7.4 Nginx reverse proxy

We wanted a reverse proxy human readable to access our applications and also have an SSL certificate/HTTPS for NextCloud, Collabora and Jellyfin.
